Latin square design

An orthogonal experimental design

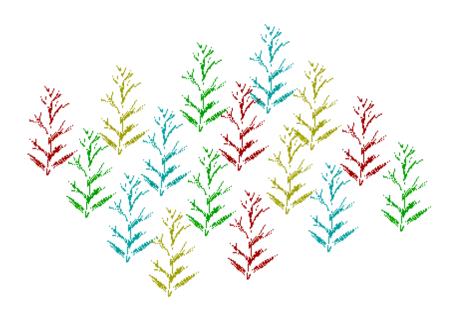

Latin square design

- Treatments are assigned within rows and columns, with each treatment once per row and once per column.
- There are equal numbers of rows, columns, and treatments (orthogonally designed).
- Useful where the experimenter desires to control variation in two different directions.

4×4 Latin square design

Different colors represent different treatments. There are 4 treatments (A-D) assigned to 4 rows (I-IV, e.g. independent days) and 4 columns (1-4, e.g. different species).

Latin square design solutions

(digits indicate treatments)

$$\begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} \quad \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 4 & 3 \\ 3 & 4 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 1 & 3 \\ 3 & 1 & 4 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 3 & 5 & 1 & 4 \\ 3 & 5 & 4 & 2 & 1 \\ 4 & 1 & 2 & 5 & 3 \\ 5 & 4 & 1 & 3 & 2 \end{bmatrix} \begin{bmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 4 & 1 & 5 & 3 \\ 3 & 5 & 4 & 2 & 1 \\ 4 & 1 & 5 & 3 & 2 \\ 5 & 3 & 2 & 1 & 4 \end{bmatrix}$$

Variance partation

Source of variation	Degrees of freedom ^a	Sums of squares (SS)	Mean square (MS)	\mathbf{F}
Rows (R)	r-1	SS_R	$SS_R/(r-1)$	MS_R/MS_E
Columns (C)	r-1	SS_C	$SS_C/(r-1)$	MS_C/MS_E
Treatments (<i>Tr</i>)	r-1	SS_{Tr}	$SS_{Tr}/(r-1)$	MS_{Tr}/MS_{E}
Error (E)	(r-1)(r-2)	SS_E	$SS_E/((r-1)(r-2))$	
Total (<i>Tot</i>)	r^2-1	\mathbf{SS}_{Tot}		

where r=number of treatments, rows, and columns.

4 III B 25.17 4 IV D 177.17

2 IV B 89. 3 I D 86.16

Example

Change in Blood Sugar Levels in Mice:
Four individuals of mice, four days, and four treatments are arranged in a Latin square design. The response is the mean change in blood sugar for 4 animals. The treatments are levels of insulin coded as follows:

Level A for 150 micro units
B 300

C 600

D 1200

Mouse	Day							
	1 2			2	3 4			4
I	В	-4.5	С	91.83	D	86.16	A	-0.17
II	D	92.33	A	-48.33	В	-78.16	С	68.83
III	С	59.83	D	168.99	A	-24.17	В	25.17
IV	A	-45	В	89	С	101	D	177.17

Model

Sugar =
$$\beta_0 + \beta_{insulin} \times insulin$$

+ $\beta_{day} \times day$
+ $\beta_{group} \times group$
+ error

Treatment factor: insulin

Intrinsic factor: day

Nonspecific factor: group

Hierarchical (nested) ANOVA

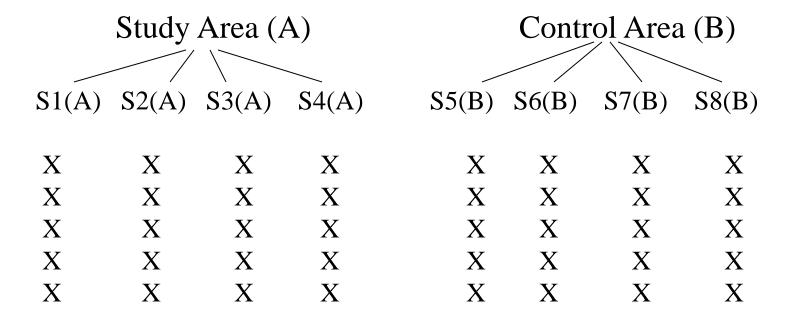

Hierarchical (nested) ANOVA

• In some two-factor experiments the level of one factor, say B, is not "cross" or "cross classified" with the other factor, say A, but is "NESTED" with it.

- The levels of B are different for different levels of A.
 - For example: 2 Areas (Study vs Control)
 - 4 sites per area, each with 5 replicates.
 - There is no link from any sites on one area to any sites on another area.

Example

There are 8 sites, not 2, not 4 either.

X = replications

Number of sites (S)/replications need not be equal with each sites.

Analysis is carried out using a nested ANOVA not a two-way ANOVA.

Nested ANOVA vs. two-way ANOVA

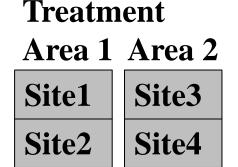

• A Nested design is not the same as a two-way ANOVA which is represented by:

	A1	A2	A3
B1	X X X X X	X X X X X	X X X X X
B2	X X X X X	X X X X X	X X X X X
В3	X X X X X	X X X X X	X X X X X

Nested, or hierarchical designs are very common in environmental effects monitoring studies. There are several "Study" and several "Control" Areas.

Objectives

- The nested design tests two things: (1) difference between "Study" and "Control" areas, and (2) the variability of the sites within areas.
- If we fail to find a significant variability among the sites within areas, then a significant difference between areas would suggest that there is an treatment effect.
- In other words, the variability is due to differences between areas (treatment) and not to variability among the sites.

Notes

- In this kind of situation, however, it is highly likely that we will find variability among the sites.
- Even if it should be significant, however, we can still test to see whether the difference between the areas is significantly larger than the variability among the sites with areas.

Statistical Model

$$Y_{ijk} = \mu + A_i + B_{(i)j} + \epsilon_{(ij)k}$$

i indexes "A" (often called the "major factor")

(i)j indexes "B" within "A" (B is often called the "minor factor")

(ij)k indexes replication

$$i = 1, 2, ..., M$$

$$j = 1, 2, ..., m$$

$$k = 1, 2, ..., n$$

Model (continued)

$$Y_{ijk} = \overline{Y}_{...} + \left(\overline{Y}_{i..} - \overline{Y}_{...}\right) + \left(\overline{Y}_{ij.} - \overline{Y}_{i...}\right) + \left(Y_{ijk} - \overline{Y}_{ij.}\right)$$

and

$$\sum_{i} \sum_{j} \sum_{k} (Y_{ijk} - \overline{Y}_{...})^{2} = \sum_{i} \sum_{j} \sum_{k} (\overline{Y}_{i..} - \overline{Y}_{...})^{2} + \sum_{i} \sum_{j} \sum_{k} (\overline{Y}_{ij.} - \overline{Y}_{i...})^{2} + \sum_{i} \sum_{j} \sum_{k} (\overline{Y}_{ijk} - \overline{Y}_{ij.})^{2} + \sum_{i} \sum_{j} \sum_{k} (Y_{ijk} - \overline{Y}_{ij.})^{2}$$

Model (continued)

Or,

$$TSS = SS_A + SS_{(A)B} + SSW_{error}$$

$$= m.n \sum_{i=1}^{M} (\overline{Y}_{i..} - \overline{Y}_{...})^{2} + n \sum_{i=1}^{M} \sum_{j=1}^{m} (\overline{Y}_{ij.} - \overline{Y}_{i...})^{2} + \sum_{i=1}^{M} \sum_{j=1}^{m} \sum_{k=1}^{m} (Y_{ijk} - \overline{Y}_{ij..})^{2}$$

Degrees of freedom:

$$M.m.n - 1 = (M-1) + M(m-1) + Mm(n-1)$$

In lecture 5, Two-way ANOVA:

$$SS_A = \sum n_B n_{AB} (\overline{X}_A - \overline{X})^2$$

$$SS_B = \sum n_A n_{AB} (\overline{X}_B - \overline{\overline{X}})^2$$

Example

M=3, m=4, n=3; 3 Areas, 4 sites within each area, 3 replications per site, total of (M.m.n = 36) data points

\mathbf{M}_1				\mathbf{M}_2					\mathbf{M}_3				Areas	
<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>		<u>5</u>	<u>6</u>	<u>7</u>	<u>8</u>		<u>9</u>	<u>10</u>	<u>11</u>	<u>12</u>	Sites
10	12	8	13		11	13	9	10		13	14	7	10	
14	8	10	12		14	11	10	9		10	13	9	7	Repl.
9	10	12	11		8	9	8	8		16	12	5	4	
11	10	10	12	-	11_	11	9	9		13	13	7	_7 -	$-\overline{Y}_{ij}$.
	10.	.75				1	0.0				_ 10	0.0	$\overline{Y_i}$.	
						1	0.25	$\sqrt{\bar{Y}}$	-					

Example (continue)

$$SS_A = 4 \times 3 [(10.75-10.25)^2 + (10.0-10.25)^2 + (10.0-10.25)^2]$$

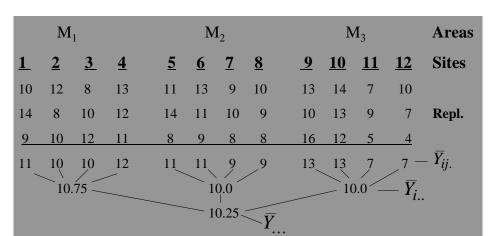

= 12 (0.25 + 0.0625 + 0.625) = 4.5

$$SS_{(A)B} = 3 [(11-10.75)^{2} + (10-10.75)^{2} + (10-10.75)^{2} + (12-10.75)^{2} + (11-10)^{2} + (11-10)^{2} + (9-10)^{2} + (9-10)^{2} + (13-10)^{2} + (13-10)^{2} + (7-10)^{2} + (7-10)^{2}]$$

$$= 3 (42.75) = 128.25$$

$$TSS = 240.75$$

$$SSW_{error} = 108.0$$

ANOVA Table for Example

Nested ANOVA: Observations versus Area, Sites

Source	DF	SS	MS	F	P
Area	2	4.50	2.25	0.158	0.856
Sites (A)B	9	128.25	14.25	3.167	0.012**
Error	24	108.00	4.50		
Total	35	240.75			
					$MS_A/MS_{(A)B}$
				↓ :	
			$= MS_{(A)}$	_B /MSV	Verror

Summary

- Nested designs are very common in environmental monitoring
- It is a refinement of the one-way ANOVA
- All assumptions of ANOVA hold: normality of residuals, constant variance, etc.
- Can be easily computed using R, SAS, MINITAB, etc.
- Need to be careful about the proper ratio of the Mean squares.
- Always use graphical methods e.g. boxplots and normal plots as visual aids to aid analysis.

Example: Hierarchical (nested) ANOVA

R results

R does not compute the correct F-statistics, because it uses the residual MS for the denominator in all calculations, which is not applicable for nested ANOVA.

The interaction sum of squares in the nested case is the sum of the subject (nested in) effect and interaction in the crossed model case, as are the degrees of freedom.

```
# Manually computation of the F-statistic and p value is needed.
```

```
fit = summary(aov(Length ~ Cage / Mosquito, dat))
```

```
F.value = fit[[1]][1, 3] / fit[[1]][2, 3]
```

```
p = pf(F.value, fit[[1]] [1, 1], fit[[1]] [2, 1], lower=FALSE); p # 0.23
```

Or, Ime() or Imer() are preferred.

```
# Another version: nested ANOVA summary(aov(Length ~ Cage + Error(Cage / Mosquito), dat))
```

```

Split-plot ANOVA

Split-plot ANOVA

The split-plot design involves two experimental factors, A and B. Levels of A are randomly assigned to whole plots (main plots), and levels of B are randomly assigned to split plots (subplots) within each whole plot.

The design provides more precise information about B than about A.

The Experiment on the Tensile Strength of Paper

			Replicate (or Block) 1		Replicate (or Block) 2			Replicate (or Block) 3			
A	Pulp Pr	reparation Method	1	2	3	1	2	3	1	2	3
	Tem	perature (°F)									
		200	30	34	29	28	31	31	31	35	32
	В	225	35	41	26	32	36	30	37	40	34
	_	250	37	38	33	40	42	32	41	39	39
		275	36	42	36	41	40	40	40	44	45

The Split-plot design

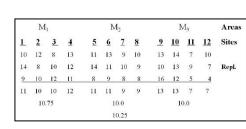

- Each replicate (sometimes called **blocks**) has been divided into three parts, called the **whole plots**
- Pulp preparation methods is the whole plot treatment, it is a hard-tochange factor
- Each whole plot has been divided into four subplots or split-plots
- Temperature is the subplot treatment
- Generally, the hard-to-change factor is assigned to the whole plots

The Experiment on the Tensile Strength of Paper

			Replicate (or Block) 1		Replicate (or Block) 2			Replicate (or Block) 3			
A	Pulp Pr	reparation Method	1	2	3	1	2	3	1	2	3
	Tem	perature (°F)									
		200	30	34	29	28	31	31	31	35	32
	В	225	35	41	26	32	36	30	37	40	34
	_	250	37	38	33	40	42	32	41	39	39
		275	36	42	36	41	40	40	40	44	45

Split-plot ANOVA

Recall that nested ANOVA has specific error variance.

As to split-plot ANOVA, each different plot size is associated with its own error variance, so instead of having one error variance (as in all the ANOVA tables up to this point), we have as **many error terms** as there are different plot sizes.

The analysis is presented as a series of component ANOVA tables, one for each plot size, in a hierarchy from the largest plot size with the lowest replication at the top, down to the smallest plot size with the greatest replication at the bottom.

Example

- Example tensile strength in paper manufacturing
 - Three pulp preparation methods
 - Four different temperatures
 - Each replicate requires 12 runs
 - The experimenters want to use three replicates

The Experiment on the Tensile Strength of Paper

F Ratios

F ratios are computed somewhat differently because there are two errors

- $F_R = MSBlock/MSE_{A:block}$
- $F_A = MSA/MSE_{A:block}$

tests the effectiveness of blocking tests the sig. of the A main effect

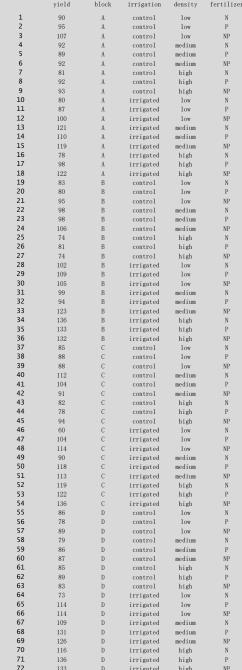

- $F_R = MSB/MSE_{A:B:block}$
- $F_{\Delta R} = MSAB/MSE_{A:B:block}$

tests the sig. of the B main effect tests the sig. of the AB interaction

Face recognition experiment

Subject	regular	90deg	inverted
1	360	320	440
2	120	220	240
3	280	340	400
4	100	80	260
5	240	260	300
6	300	320	380
7	120	140	240
8	400	400	460

m1 = 240 ms m2 = 260 ms m3 = 340 ms

Repeated Measures

- 'Default' design: 10 subjects (students) give an observation for condition A, 10 other subjects give an observation for condition B, and another 10 subjects give an observation for condition C.
- Repeated measures design: 10 subjects give an observation for condition A and the same 10 give an observation for condition B and C.
- Condition A, B, and C are usually associated.

Why should we change the "regular" ANOVA to RM designs?

Repeated measures ANOVA is used when all members of a random sample are measured under a number of different conditions. As the sample is exposed to each condition in turn, the measurement of the dependent variable is repeated.

Using a standard ANOVA in this case is not appropriate because it fails to model the correlation between the repeated measures: the data violate the ANOVA assumption of independence.

Keep in mind that some ANOVA designs combine repeated measures factors and nonrepeated factors. If *any* repeated factor is present, then repeated measures ANOVA should be used.

"Regular" ANOVA

- Face recognition experiment:
 - Subject1 does condition A, subject2 does condition B
 - Mean rate for A = 500 ms, for B = 600 ms

- Interpretation 1: condition A is easier
- Interpretation 2: subject1 is faster

Increase power

- In an ANOVA we're always looking at the size of the ratio between the variance between conditions and the 'rest of' the variance—the **unexplained** part (estimated by the average variability within a given condition).
- The more of the unexplained part you can explain and get out of the denominator, the better the chance for the ratio to come out big enough to pass the F test.
- Explaining the variance due to individual differences between subjects is one way of doing this.

Applications

First, some research hypotheses require repeated measures. Longitudinal research, for example, measures each sample member at each of several ages. In this case, age would be a repeated factor.

Second, in cases where there is a great deal of variation between sample members, error variance estimates from standard ANOVAs are large. Repeated measures of each sample member provides a way of accounting for this variance, thus reducing error variance.

Third, when sample members are difficult to recruit, repeated measures designs are economical because each member is measured under all conditions.

Example: face recognition experiment

- 8 participants
- 3 conditions: normal, 90-degree turn, 180-degree turn (inverted)

• Measure: rate to recognize

Data of face recognition experiment

Subject	regular	90deg	inverted
1	360	320	440
2	120	220	240
3	280	340	400
4	100	80	260
5	240	260	300
6	300	320	380
7	120	140	240
8	400	400	460

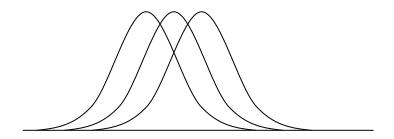

m1 = 240 ms m2 = 260 ms m3 = 340 ms

Regular 1-way ANOVA

- Global Mean = 280 ms
- Total variance (SS_tot) = 277600
 - Variance for all 24 data points from each other
- Between-conditions variance
 (SS_bet) = 44800
 - Variance of the three condition mean rates (means for regular, 90deg, & inverted)

Regular 1-way ANOVA

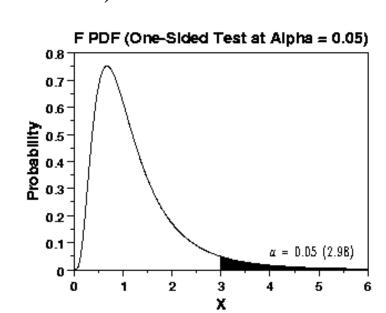

- Within condition variance (SS_w) = 232800
 - 'left-over' or 'error' or 'unexplained' variance
 - Conceptually, sum of the variances for each of the three conditions considered separately

 Calculated by just subtracting the SS_bet from the SS_tot (that's why it's 'left over')

Regular 1-way ANOVA

- MS_bet = SS_bet/df_bet
 - = 44800 / (# of conditions -1)
 - =44800 / 2 = 22400
- $MS_w = SS_w / df_w$
 - = 232800 / (# of datapoints # conditions)
 - = 232800/21 = 11805
- F ratio = MS_bet / MS_w = 2.02
- F = 2.02 not significant at alpha = .05!

What's the problem?

	regular	90deg	inverted
1	360	320	440
2	120	220	240
3	280	340	400
4	100	80	260
5	240	260	300
6	300	320	380
7	120	140	240
8	400	400	460

Each subject shows the same pattern (regular fastest, inverted slowest), but there's a lot of variability in the absolute times because the subjects differ in their average speed.

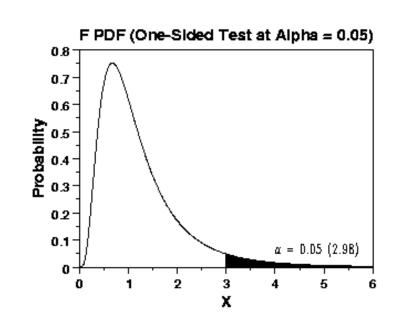

- Within condition variance (SS_w) = 232800
- But now we know how to explain some of the 'unexplained' variance
 - If we take the subject variance out of SS_w, there'll be less variance 'left over'

• Break up the SS_w into SS_subj and SS_inter

Often known as SS_err

- Remember that $SS_w = 232800$
- Subject variance (SS_subj) = 219200
 - ➤ Variance of the mean rates (averaged over all conditions) for each of the 8 subjects
 - >= 94% of the original SS_w variance!
- Interaction (error) variance (SS_inter) = 13600
 - Leftovers after subject variance subtracted out (SS_w - SS_subj)

- MS_bet = SS_bet/df_bet = 44800 / (# of conditions -1)
 - = 22400
- MS_inter = SS_inter / df_inter = 13600 / (df subj=7 × df_bet=2) = 971
- F ratio = MS_bet / MS_inter = 23.0
- F = 23.0 way above significance cutoff!

- In a repeated measures design it is possible to partition subject variability from the **treatment** and **error** terms.
- In such a case, variability can be broken down into between-treatments variability (or within-subjects effects, excluding individual differences) and within-treatments variability.
- The within-treatments variability can be further partitioned into **between-subjects variability** (individual differences) and **error** (excluding the individual differences)

Assumptions of RMANOVA

- Independent random sampling
- Normal distribution (doesn't really matter if sample is not tiny)
- Homogeneity of variance (need same number of observations for each condition)
- Homogeneity of covariance (sphericity)
 - This actually matters and can be a pain

Sphericity

- If homogeneity of covariance holds, your population/sample is said to have sphericity.
 - Basic idea of sphericity: there is no tendency for subjects to pattern together more on some conditions than on others
 - Unfortunately, it is pretty common in the real world that you do NOT have sphericity

	regular	90deg	inverted
1	360	320	440
2	120	220	240
3	280	340	400
4	100	80	260
5	240	260	300
6	300	320	380
7	120	140	240
8	400	400	460

Sphericity

- Sphericity is the property that the degree of interaction (covariance) between any two different levels of the independent variable is the same.
- Sphericity is critical for RM ANOVA because the error term is the average of the pairwise interactions.

• Violations generally lead to inflated F statistics (and hence inflated Type I error).

Sphericity

- How to find out whether you have it or not: Mauchly test. mauchly.test()
- How to correct: use a more conservative F value, e.g. Greenhouse-Geisser or Huynh-Feldt
- Multivariate ANOVA (MANOVA) is an alternative to RMANOVA which is not so sensitive to violations of sphericity

mauchly.test()

```
# data
"C"."C"."C"."C"."C"."C"."C")

Summary of GLM

Commonly used tests, based on the General Linear Model.

Analysis	Response Variable	Explanatory Variable	Interaction	Comments
t-test	1 ratio	1 nominal	Absent	compares two means
1-way ANOVA	1 ratio	1 nominal	Absent	compares 3 or more means in 1 category
2-way ANOVA	1 ratio	2 nominal	Present	tests for interactive effects compares means in 2 categories, if no interaction
Paired Comparison	1 ratio	2 nominal	Assumed Absent	compare 2 means in 1 category, controlled for 2nd category(blocks or units)
Randomized Blocks	1 ratio	2 nominal	Assumed Absent	compare 3 or more means in 1 category, controlled for 2nd category(blocks or sampling units)
Hierarchical ANOVA	1 ratio	≥2 nominal	Absent	nested comparisons of means
ANCOVA	1 ratio	≥ 1 ratio	present	compares two or more slops
		≥ 1 nominal	Absent	compares means, controlled for slopes
Regression	1 ratio	1 ratio	Absent	tests linear relation of response to explanatory
Multiple Regression	1 ratio	≥ ratio	Assumed Absent	tests linear relation to 2 explanatory variables relation expressed as a plane

Mixed effect models

Mixed-effects models

Fisher's ANOVA treated all categorical explanatory variables as if they were the same.

It was Eisenhart (1947) who realized that there were actually two fundamentally different sorts of categorical explanatory variables: he called these fixed effects and random effects.

- Fixed model: generalize the results to experimental values used in the study.
 - drug, placebo; male, female;
- Random model: make inferences beyond the particular values of the study
 - sites, individuals

Fixed and random effects

- Mixed model: fixed + random
 - fixed effects influence only the mean of y;
 - random effects influence only the variance of y.

The random effects come from a large population, there is no point in concentrating on estimating means of our small subset of factor levels, and no point in comparing individual pairs of means for different factor levels.

Much better to recognize them for what they are, random samples from a much larger population, and to concentrate on their variance.

Random effects model: a one-way ANOVA

$$Y_{ij} = \mu + \alpha_i + \epsilon_{ij}$$
 $i = 1,..., a levels; j = 1,..., n obs.$

where the α and ϵ have mean zero, but variances σ^2_{α} and σ^2_{ϵ} respectively.

$$\sigma^2_{\varepsilon} = SSE/(a(n-1)) = MSE$$

$$\sigma^2_{\alpha} = (MSA - MSE) / n$$

Common cases

- Mixed-effects models are particularly useful in cases where there is
 - temporal pseudoreplication (repeated measurements)
 - spatial pseudoreplication (e.g. nested designs or split-plot experiments).

Mixed effect models for spatially autocorrelated data

```
# plot 5 autocorrelation types in package nlme
library(nlme)
par(mfrow=c(2,3))
D <- seq(from = 0, to = 1, by = 0.1); Mydata <- data.frame(D = D)

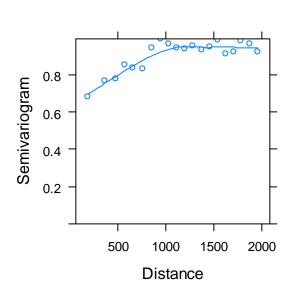

autocor <- corSpher(c(0.8, 0.1), form = ~ D, nugget = TRUE)
autocor <- lnitialize(autocor, data = Mydata)
semivar <- Variogram(autocor)
plot(semivar[,2], semivar[,1], type = "I", col = 1, xlab = 'Distance', ylab = 'Semivariogram', main = 'corSpher')
```

- Exponential correlation using the function corExp.
- Gaussian correlation using the function corGaus.
- Linear correlation using the function corLin.
- Rational quadratic correlation using the function corRatio.
- Spherical correlation using the function corSpher.

Mixed effect models for spatially autocorrelated data

```
# Mixed effect model (Zuur)
Boreality <- read.table('D:/softwares/R/library/AED/data/Boreality.txt', header=T)
head(Boreality)
# Mixed effect models (Zuur, Page 168)
library(nlme)
f1 <- formula(nBor ~ Wet)
B1.gls \leftarrow gls(f1, data = Boreality)
Vario.gls \leftarrow Variogram(B1.gls, form =\sim x + y,
              robust = TRUE, maxDist = 2000,
              resType = "pearson")
plot(Vario.gls, smooth = TRUE)
```

```
B1A <- gls(f1, correlation = corSpher(form =~ x + y, nugget = TRUE), data = Boreality)
B1B <- gls(f1, correlation = corLin) (form =~ x + y, nugget = TRUE), data = Boreality)
B1C <- gls(f1, correlation = corRatio (form =~ x + y, nugget = TRUE), data = Boreality)
B1D <- gls(f1, correlation = corGaus (form =\sim x + y, nugget = TRUE), data = Boreality)
B1E <- gls(f1, correlation = corExp (form =\sim x + y, nugget = TRUE), data = Boreality)
AIC(B1A, B1B, B1C, B1D, B1E)
```

R script – nested ANOVA

Distinct names for the variables in factorB, like this; then just having factorB as a random effect, is sufficient.

factorA	factorB	response
bob	bob1	6
bob	bob2	8
bob	bob3	12
jane	jane1	9
jane	jane2	7
jane	jane3	10
1 /	C	4 A 1 11C 4

lme(response ~ factorA, random=~1|factorB)
#library(nlme)

Same coding for the variables in factorB for each level of factorA, then just having factorB as a random effect is not correct; you instead need the random effect to be the interaction between them.

```
factorA factorB
bob rep1
bob rep2
bob rep3
jane rep1
jane rep2
jane rep3
```

lme(response ~ factorA,

random=~1|factorA:factorB)

R code

```
# Split-plot design
Model = aov(Y \sim A*B + Error(block/A), data = D)
library(nlme)
model1 = Ime(Y ~ A*B, random=~1|block/A, data=D)
library(lme4)
model2 = Imer(Y \sim A*B+(1|block/A), data=D)
# Hierarchical ANOVA
Model = aov(Y \sim A / B, data = D)
# Repeated measures ANOVA
Model = aov(Y \sim Time + Error(Subject / Time), data = D)
Model = aov(Y ~ Time + Error(Subject), data = D) # same
model = Ime(Y ~ Treat*Time, random = ~1| Subject, data = D)
# Randomized Block Design
library(lme4)
Model <- Imer(Y ~ treat + (1|group), data = D) # mixed effect model
## SS - residual sum of squares for mixed effect models
sum(resid(Model)^2)
```

Notes for experiment design

Control

We recommend planned comparisons (contrasts) rather than unplanned multiple comparisons. In most cases, you are not interested in comparing all possible groups, but can identify particular questions that are of greater interest.

Balance

Aim for equal sample sizes. The linear model calculations can easily handle unequal samples, but the analysis is more sensitive to the underlying assumptions and parameter estimates and hypothesis tests will be more reliable if sample sizes are equal.

Normality

For moderate violations of normality and homogeneity of variances, we recommend proceeding with the analysis, but being cautious about results that are marginally significant or non-significant. Otherwise we recommend using generalized linear models when the underlying distribution of the response variable can be determined, or one of the robust tests.

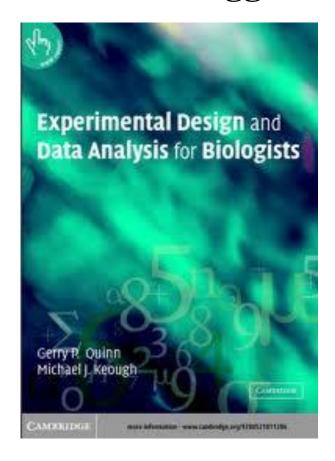

Homogeneity of variances

Homogeneity of variances is an important assumption. ANOVA is robust to small and moderate violations (especially with equal sample sizes), but big differences (e.g. manyfold differences between largest and smallest variances) will alter the Type I error rate of the *F* test.

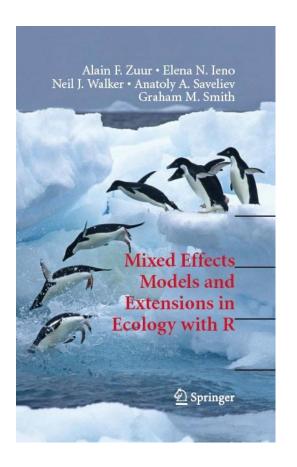

Checking assumptions

Examine homogeneity of variances with exploratory graphical methods, e.g. look at the spread of boxplots, plot group variances or standard deviations against group means, or plot residuals against group means and look for patterns.

Suggested books for ANOVA

Quinn, G. P. and Keough, M. J. 2002. Experimental design and data analysis for biologists. Cambridge University Press.

Zuur, A., et al. 2009. Mixed effects models and extensions in ecology with R. Springer.

Assignment

General objectives: learn two-way ANOVA.

- Generate your own data (In order to better understand an interaction in a 2-way ANOVA, you create data that has an interaction with a P <.05. Please describe the experiment and data for interpretation purposes.)
- Provide a brief introduction to the data set,
- Formally state the hypotheses that you are going to test (Ho's and Ha's),
- Satisfy assumptions of normality of residuals, homogeneity of variances, and independency of residuals, homogeneous of residuals
- Provide a print out's of the data set, programs and their output.
- Indicate in your results and discussion section what you found, i.e. did you reject your null, and the conclusions that you have drawn from the analysis. Since there will be an interaction (P<0.05) then you must break apart your factors and do 1-way ANOVA.

R script

```
# Bartlett Test of Homogeneity of Variances (parametric)
bartlett.test(split(Dat$y, list(Dat$x1, Dat$x2)))
bartlett.test(Dat$y ~ Dat$x1 * Dat$x2)
# Two Way ANOVA
weight.gain=data.frame(ID=1:60, amount=NA, food=NA, gain=NA)
n=0
for(i in c('high','low')){
           for(j in c('beef','cereal','port')){
                      for(k in 1:10){
                      n=n+1
                      weight.gain$amount[n]=i
                      weight.gain$food[n]=i
